MORPHOMETRY, GROWTH, AND AGE OF TUNAS

SPECIAL SCIENTIFIC REPORT: FISHERIES No. 22

UNITED STATES DEPARTMENT OF THE INTERIOR FISH AND WILDLIFE SERVICE

Explanatory Note

The series embodies results of investigations, usually of restricted scope, intended to aid or direct management or utilization practices and as guides for administrative or legislative action. It is issued in limited quantities for the official use of Federal, State or cooperating agencies and in processed form for economy and to avoid delay in publication.

Measurements of Yellowfin Tuna from the Equatorial Countercurrent Area

The writer has previously reported in this journal how he measured yellowfin tuna (taken on longlines) from Palau waters and determined their ares by consulting an age-length table. The majority of the tuna taken were in their seventh year; eighth-year and sixth-year fish were next most numerous.

Past fishery investigations have shown that fish in their fourth year, and some as young as the second year, are caught near the islands (the so-called "resident fish"), but the yellowfin which migrate continually in the currents of the open sea have rarely been found to be younger than the fourth year.

Although these facts were obtained from the results of a survey conducted in the waters off Palau, they coincided in general with those obtained in the later survey carried out in the waters south of the Marshall Islands.

Since it was thought that it would be possible to get a general knowledge of the morphometry of yellowfin tuna inhabiting the South Sea area by conducting a survey midway between the two archipelagoes, that is, in the waters south of Truk, Ponape, Kusaie and Jaluit islands, we waited for an opportunity to gather data in that area. When at a later date the survey ship Zuiho Maru carried out fishing ground surveys in that area, we measured the yellowfin taken there. The results of these measurements are compiled in this article.

As seen under the column heading of current direction, every one of the grounds surveyed at that time is shown to be in the area of easterly currents. We can definitely assume from this fact that the fishing grounds were within the Equatorial Countercurrent. The title of this article therefore, can be justified.

The data contained in the tables which follow can be summarized as follows:

| | Table 1 | out of 2 | 7th-year fish | 1 |

| (TN. | *Presumed | to | be out | of | 66 | with | 7th- | year | fish 37 |) | |

The majority of the yellowfin caught in this area were in their seventh

year; next most numerous were 8th-year and 6th-year fish. The data clearly indicate that yellowfin under the 4th-year were not caught.

I took great pains in measuring these yellowfin in order to learn the age of the fish taken by tuna longlines in island waters. Although this was the objective, I felt my interest mount as I accumulated more and more measurements for I was able to obtain strong evidence of the permanent nature of the tuna fishing industry of the islands.

Bricfly, the fact that the tuna longline, which is the principal gear used in tuna fishing, takes only the mature yellowfin and does not catch those below the 4th-year or those which are immature means that the fishery is conducted according to the natural law of spawning protection. (Although young and immature yellowfin are sometimes caught in the waters hear the island, such instances are rare and insignificant.) For this reason, I believe that the stock of this tuna species is of a permanent nature.

The Correlation Between the Length and Weight of Yellowfin Tuna

Based on measurements taken aboard the Shonan Maru during the course of experimental tuna fishing in 1934. January 1935.

I Introduction

This paper is an attempt to show the correlation between the lengths and weights of 44 yellowfin tuna taken during experimental tuna fishing in 1934.

II Method of Measuring Length and Weight

The fish were weighed in the condition in which they were when captured and their lengths were taken as the horizontal distance between the snout and the end of the base of the caudal (see the accompanying sketch). The units of measurement employed were kilograms and centimeters.

III Summary

As is clearly shown by Figure 1, the coordinates of each specimen were found by representing the weights (W) on the X axis and the lengths (L) on the Y axis. The line XY was found by the "method of great majority" [sic]. The line XY satisfies the equation $L = aW^{b}$. In other words, if a number of points are taken at random on this line, a line connecting the points whose coordinates are represented by Log 10 L Log 10 W of these points taken at random can be considered to be roughly a straight line, as shown in Figure 2. If we calculate the constants a and b of the equation $L = aW^{b}$ in Figure 2, they are as follows:

a = 40.12 b = 1/3 Accordingly we arrive at the equation L = 40.12W 1/3 IV Conclusion

As shown in the preceding paragraph, the correlation between the lengths and weights of yellowfin tuna within the range of 5 to 60 kg taken within this area at this season can in general be shown by the formula given in Paragraph III.

[Figure 1 is a scatter diagram of the lengths and weights with a curve fitted to it. Figure 2 is a graph with a straight line connecting points whose coordinates are the logs of weights and lengths. There is also a sketch of a tuna showing what measurement was used for L.]

Growth Curves of Blue-Fin Tuna and Yellow-Fin Tuna Based on The Catches

Synopsis [in English]

No investigation has been made on the scale and otolith of the tuna from the Seas of Japan with reference to the growth rate of the fish. In the present paper are given frequency histograms (Figs. 2 and 5) showing body-weight distribution of bluefin tuna (Thunnus orientalis Temminck & Schlegel) and yellowfin tuna (neothunnus macropterus Temminck & Schlegel) from Shigedera fishing ground which is situated at north-eastern corner of the Suruga Bay (Fig. 1). The data were obtained from 1924 to 1931 inclusive, and can be divided into several age-groups as plotted in Figs. 4 and 6, in which solid circle indicates individual fluctuation of the body-weight and encircled dot shows the average body-weight of a large number of specimens which were caught there at the same time and nearly of the same weight. The curves are free-hand smoothing. [end of English synopsis]

It is difficult to find out the growth of fishes which migrate widely in the oceans, and the study of annuli and otoliths is still not very far advanced. The author has used data on the weights of individual fish from the records of catches of black tuna and yellowfin tuna on the Shigedera fishing grounds in the northeastern corner of Suruga Bay (Fig. 1), and has deduced the growth rates of the fish taken on those grounds on the basis of graphs of the weight distributions.

Young black tune are first taken in the large set-nets of these fishing grounds around July and August, and thereafter some are taken every day. From the end of the year through the early part of the following year these fish are from 2 to 4 kg in weight; in the peak season of April, May, and July they weight about 5 kg; and in the spring of their third year they attain a weight of about 10 kg. During this period they are called small meji, medium meji, and large me ji depending on their weight. In the spring of the third year from about March and April these second-year fish (large meji) disappear completely from the catch, and the only fish taken after this time are either first-year fish or those much larger than the second-year fish. If we except these young fish and separate the large black tuna which are taken by weight groups, we get a graph of weight distribution like that shown in Fig. 2. This graph can be divided according to the differences in the weights of the fish into three groups of small, medium, and large tuna. Although from 1924 to 1928 the average weights of the fish in the small and medium groups tended gradually to increase, it can be seen in Fig. 3, which shows the fishing season for each group, that the season for small and medium fish was coming later each year and it may be thought that the increase in the average weights was related to this lag.

Since it was already possible to ascertain clearly the rate of growth for fish under the second year of age, we were able, by considering the abovementioned three groups of small, medium, and large fish to be respectively third-, fourth-, and fifth-year fish, to draw a growth curve for the black tuna as shown in Fig. 4. However, the rate of increase in the body weight in the summer season appears to be greater than that shown for the summer season in the corresponding portion of the smoothed growth-rate curve covering a sixyear period, and marked differences are noticeable in the case of the fourthand fifth-year fish. This leads one to believe that there is a marked difference between summer and winter growth. Only one or a few fish of the sixth year and older are taken each year and it is therefore not possible to find their rates of growth. The catch of yellowfin tuna, both adults and young, on these grounds is a great deal smaller than that of black tuna, and the season is limited to the summer. Excluding the young yellow <u>mail</u>, the weight distribution was sought for yellowfin weighing over 10 kg. The graph of this distribution is shown in Fig.5 where it can be seen that the maximum values for the number of fish of each size in the catch are rather widely separated. If we take these as the average weights for yellowfin of each age in the summer season and plot a growth curve, we get the result shown in Fig.6. In the case of yellowfin over 50 kg in weight the maximum values for the number of fish in the catch are not clear, the number of fish is small, and accordingly their growth rate is unknown.

On the Age of Yellowfin Tuna from Palau Waters by Kenzo Ikebe, Technician

[from South Sea Fishery News, Vol.3, No.10. December 15, 1939]

Data on the lengths and weights of fish are of great value as reference materials for the study of the grounds where the fish were taken. For this reason the author took measurements of 11 yellowfin tuna taken on the long lines of the Hakuo Maru November 14 west of Palau (position of fishing grounds, 7° 10' N, 134° 3' E).

The following table shows the results of measurements of the body length, total length, body depth, body width, and weight as well as the condition factor ($\frac{W}{L^2}$ X 1,000) calculated according to the method published by Mr. Kinosuke Kimura of the Central Fisheries Experiment Station.

| No. | Total Length | Body Length | Body Depth | Body Midth | Weight | Condition Factor |
|-------------------------------------------|-------------------------------------------------------------|-------------------------------------------------------------|----------------------------------------------------|----------------------------------------------------------------------|------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| | CIL | Çm | ÇM. | <u>CH</u> | Kg. | |
| 1 2 3 4 5 6 7 8 9 | 158 138 141 141 149 141 133 145 152 | 133 114 116 117 123 118 113 125 129 | 34 27 31 31 33 31 25 30 30 | 27 23 25 26 25 23 22 23 22 23 25 25 | 49.1 31.8 37.0 38.6 42.3 37.2 31.4 43.0 48.7 38.8 | 20.9 21.5 23.7 24.1 22.7 22.6 21.8 22.0 22.7 21.9 |
| 11 | 135 | 121 114 | 29 | 24 | 34.1 | 23.0 |

Table 1

The author then calculated the condition factors for two sets of data which had been collected aboard the Hakuo Maru before he reported for duty at this Station. These data are segregated by sexes and one set was taken from 11 yellowfin caught east of Palau on May 11 of this year (position of fishing ground, 7° 18' N, 134° 42' E) while the other set represents 14 yellowfin taken May 14 at 7° 21' N, 134° 44' E. These data are given in the following tables.

According to a study by Dr. Hiroaki Aikawa entitled "The Age of Fishes and Changes in Their Length and Weight" which was published in Volume 4, Number 11, of <u>Marine Fisheries</u> [Kaiyō Gyogyō], it is possible to find the age of a fish by comparing its weight and length with the figures supplied in a table. (This study originated in the relationship between the length and weight and the vertebral bones of fishes, and was published in Volume 7, Number 2, of the <u>Bulletin</u> of the Japanese Society of Scientific Fisheries.)

The author was greatly impressed and interested when he learned of the existence of such an extremely valuable thing as a ready reference table on the age of fish, and decided to try to compare the results of these three sets of

| DOGCIOS VOLIUNIIU CUL | Species | vellowfin | tuns |
|-----------------------|---------|-----------|------|
|-----------------------|---------|-----------|------|

Now if we compare the fish listed in Table 1 with these figures, No.1 is in its eighth year, No.2 corresponds to the sixth year in length but to the seventh in weight, No.3 to No. 6 are all in their seventh year, No.7 is in its sixth year by length and in its seventh year by weight, No.8 is a seventh-year fish, No.9 is seventh-year in length and eighth-year in weight, No.10 is a seventh-year fish, and No.11 is within the sixth-year length range and the seventh-year might range. The following figures show in abbreviated form the age determinations for the fish listed in Tables 1, 2, and 3.

| in | Table | 1 | sixth or seventh year seventh year seventh or eighth year eighth year | 3 6 1 1 | fish fish fish fish |
|----|-------|---|--------------------------------------------------------------------------------|------------------|------------------------------|
| | | | OTRUM LOOT | - | |

total 11 fish

| in Table 2 | fifth or sixth year | 1 | fish |
|------------------|------------------------------------|----|---------|
| | seventh year | 9 | fish |
| | eighth year | i | fish |
| | total | 11 | fish |
| in Table 3 | fourth or fifth year | 1 | fish |
| | seventh year | 13 | fish |
| | total | 14 | fish |
| Combining all of | these data we find that of a total | of | 36 fish |
| | seventh year | 28 | fish |
| | sixth or seventh year | 3 | fish |
| | eighth year | 2 | fish |
| | fourth or fifth year | 1 | fish |

From a consideration of these data we can conclude that among the yellowfin tuna taken on long lines in Palau waters recently fish in their seventh year predominate with some admixture of both older and younger year classes,

fifth or sixth year..... 1 fish seventh or eighth year..... 1 fish

It is the author's intention to obtain as much accurate data as possible hereafter and to use these data to investigate the ages of skipjack and albacore as well as yellowfin tuna not only in Palau waters but everywhere in the archipelago. (December 1)

Measurements and Ages of Tuna from Palau Waters by Kenzo Ikebe, Technician

[from South Sea Fishery News [Nanyo Suisan Joho], Vol.4, No.1. February 5, 1940]

In the preceding number of this journal the author published a paper on the ages of yellowfin tuna from Palau waters. In presenting a second paper on this subject there is some danger of repetition, but since it is thought that in attempting to determine the age of fish by measuring their length and weight the more data the study is based on the more accurate and reliable will be the results, the author has decided to attempt to write something more on the subject.

Last December on the second cruise of the Nanko Fishing Company's Awa Maru (92 tons, 185 horsepower) after her arrival from Japan she operated on the fishing grounds within a radius of 100 miles to the southeast of Palau. On December 23 a big catch was made at a point 40 miles southeast by south of the Palau lighthouse. Length and weight were determined on 10 spearfish [Makaira mitsukuri1], 35 big-eyed tuna [Parathunnus mebachi], and 51 yellowfin tuna [Neothunnus macropterus] from this catch. These data are given below.

These measurements were taken when the catch was being weighed while the fish were being transferred from the Awa Maru to the freighter Ebon Maru. In order not to interfere with the work it was necessary to do the measuring as rapidly as possible and so only the body lengths and weights were taken, the total length, body depth, and body width being omitted.

Body length was measured from the snout to the caudal peduncle, and the weights were taken after the fish had been completely eviscerated.

| Table . | 3] | Neothunnus | macropterus |
|---------|-----|------------|-------------|
|---------|-----|------------|-------------|

Unfortunately Tables 1 and 2 can only show the sizes of the fish because no study has been published as yet on a ready reference table of the ages of spearfish and big-eyed tuna. A comparison of the yellowfin tuna data in Table 3 with the age-class table using the same method as reported in the preceding number of this journal gives the following results:

| total 51 fish | seventh year | 41 | fish |
|---------------|-----------------------|----|------|
| | eighth year | 4 | fish |
| | sixth year | 4 | fish |
| | sixth or seventh year | 2 | fish |

It is thought that these figures have further confirmed the fact that the majority of the yellewfin tuna taken on long lines in Palau waters are fish in their seventh year. (Since the table of age-classes was published in the preceding number it has been omitted here.)

Measurements of Yellowfin Tuna from South of the Marshalls by Kenzo Ikebe, Technician [from South Sea Fishery News [Nanyo Suisan Joho], Vol.4, No.2.]

from South Sea Fishery News [Nanyo Suisan Joho], Vol.4, No.2.] March 5, 1940

From March to June of 1939 the South Seas Colonization Company's boat, the Ebon Maru (195 tons, 320 HP), with the Company's Technician Haruo Watanabe and Assistant Technician Seiichi Shimada aboard, carried out experimental tuna longlining in waters south of the Marshalls. The following is the result of an attempt to determine the ages of the yellowfin tuna reported in the catch data from that cruise.

| No . | Body Length | Weight | No | Body Length | Weight |
|-----------------------|----------------------------------------------|--------------------------------------|------------------------|--------------------------------------|---------------------------------------|
| 6.403 e (196 e C) 2+3 | meters | kan | | meters | kan |
| 1 2 3 4 5 | 1,20 1,20 1,20 1,20 1,20 1,20 | 8.60 9.60 8.90 7.60 8.40 | 6 7 8 9 10 | 1.30 1.20 1.20 1.30 1.20 | 10.30 9.10 9.30 9.10 7.60 |

A comparison of these figures in order beginning with Table 1 with the egaclass table used in the preceding number of this journal gives the following results:

| in | Table | 9 - | sixth year | fish fish fish fish | total | 12 fiah |
|----|-------|--------|-----------------------|------------------------------|-------|---------|
| in | Table | 2 | seventh year 4 | fish | total | 4 fish |
| in | Table | 3 | sixth or seventh year | fish fish fish | total | 13 fish |

| in Table | 4 | sixth or seventh year 1 seventh year 4 | fish fish | total | 5 f i sh |
|----------|---|-------------------------------------------|----------------------|-------|-----------------|
| in Cable | 5 | seventh year 2 | fish | total | 2 fish |
| in Table | 6 | sixth year 1 sixth or seventh year | fish fish fish | total | 29 fish |
| in Table | 7 | sixth or seventh year | fish fish | total | 10 fish |

If the above data are combined we get a total of 75 divided as follows:

| sixth year | fish |
|--------------------------|------|
| sixth or seventh year11 | fish |
| seventh year | fish |
| seventh or eighth year 1 | fish |
| e'ghth year1 | fish |

According to this the majority of the yellowfin taken on long lines in the waters south of the Marshalls are fish in their seventh year with only a small admixture of fish of older and younger year classes.

A comparison of the yellowfin tuna inhabiting Palau waters and those which occur south of the Marshalls shows that as far as body measurements are concerned they are almost identical, and it is therefore not difficult to deduce that they belong to the same stock of migratory fish. (February 7)

On the Measurements of Albacore and Yellowfin Tuna from Saipan Waters by Kenze Ikebe, Technician

[from South Sea Fishery News [Nanyo Suisan Joho], Vol.4, No.5. July 30, 1940]

In May of this year a survey was made aboard the research vessel Zuiho Maru of the albacore fishery around the northern outlying islands of Saipan. The general results of the investigation have been reported elsewhere so I have decided to report in this journal only on those phases having to do with the size and age of albacore and yellowfin tuna, basing my remarks on the data collected during the course of the survey.

This survey was conducted during the period from May 5 to May 28. The area covered was the waters around the outlying islands north of Saipan between 144° 45' and 146° 25' east longitude and 18° 11' and 21° 55' north latitude.

During the course of these investigations a total of 8 albacore and 58 yellowfin were taken (all on long lines). The following table shows the lengths and weights of these fish, the ages deduced from these measurements, and the dates and positions of capture.

It should be noted that the weights are those of eviscerated fish.

P LONG LONG Weight Age No. Date Position Body Length kan Cm 18°22'N, 145°13'E 1 5-5 6.70 9 102 2 11 6.00 8-9 102 3456 11 Ħ. 11 95 4.80 19°50'N, 14,5°02'E 9 5-22 7.50 110 11 8-9 102 5.70 20°07'N, 145°14'E 5-27 105 6.70 9 7 8-9 5-28 19°04'N, 145°48'E 99 4.80 8 11 5.60 R_9 102

Table 1 Albacore [Thunnus gerno]

The age determinations in the table are, as in the preceding papers of this series, based on the article by Dr. Aikswa entitled "The Age of Fishes and Changes in Their Length and Weight" (see <u>Woring Fisheries</u> [Kaiyō Gyogyō], Volume 4, Number 11). Of the 8 albacore 3 fall in the ninth-year class and 5 can be considered to be either eighth- or ninth-year fish. In the case of albacore those within the ranges of 4.80 - 6.40 kan in weight and 85 - 94 cm in length are considered to be in their eighth year, and those over 6.40 kan in weight and 94 cm in length are regarded as being in their ninth year. Judging from the fact that the oldest albacore are ninth-year fish, we can see that the albacore which migrate into Saipan waters, although they are very scarce numerically, belong almost entirely to the largest and oldest part of the stock.

[Table 2 continued]

(Note) The four fish from No. 28 to No. 31 were weighed without being gutted because of their small size.

When we examine separately the fish taken from May 21 to May 27 and those taken on May 28, we find that the 27 fish in the former group fall into the following age classes:

Thus these fish resemble those taken at Palau and south of the Marshalls (described by the author in three previous articles in this journal) in that seventh-year fish are in the majority with an admixture of a few fish from the adjacent older and younger year-classes.

Of the 31 fish in the latter group the number in each age class is as follows:

| seventh year | 1 | fleh |
|-----------------------|---|-------|
| sixth or seventh year | 1 | fi sh |
| sixth year | 8 | fish |
| fifth or sixth year | 6 | fish |
| fifth year | 7 | fish |
| fourth or fifth year | 2 | fish |
| fourth year | 1 | rish |
| second or third year | 3 | fish |
| third year | 1 | fish |
| second year | 1 | fish |

In this group the seventh-year fish are outnumbered by the sixth-year and fifth-year fish, and there is an admixture of young fish of the fifth, fourth, third, and second year-classes which makes this sample differ greatly in age composition from any yellowfin tuns which I have examined hitherto. Of particular interest is the second-year fish 51 cm in length and 730 <u>momme</u> in weight which was the smallest yellowfin taken in the course of the survey. The presence of such a young fish makes one think that the spawning grounds of the yellowfin tuna cannot be far from this area.

* * *

Dr. Aikawa's table of the age of fishes correlated with length and weight ranges

| Age | Len | gth | Weight | | |
|----------------------------------|---------|-------------------|--------------|-----------------|--|
| Fish of the year (0 age group) | 27 cm | 0.9 <u>shakri</u> | 0.49 kg | 0.13 <u>kan</u> | |
